कार्यालय कलेक्टर (खनिज शाखा) जिला शाजापुर (म.प्र.)

क्रमांक / 486 / खनिज / 2022

शाजापुर, दिनांक 22/09/2022

प्रति,

✓ सदस्य सचिव,
राज्य स्तरीय विशेषज्ञ आंकलन समिति
म.प्र. पर्यावरण परिसर ई-5 अरेरा कालोनी भोपाल (म.प्र.)

विषय:- 595 राज्य स्तरीय विशेषज्ञ आंकलन समिति की बैठक दिनांक 22.09.2022 में जिला शाजापुर की रेत सर्वेक्षण रिपोर्ट में चाही गई जानकारी के सम्बंध में।

उपरोक्त विषयांकत जिले की रेत खदानों में रेत मात्रा का ऑकलन जिला सर्वेक्षण रिपोर्ट तैयार करने हेतु गठित समिति के द्वारा मौका निरीक्षण कर किया गया।

अतः अनुरोध है कि राज्य स्तरीय विशेषज्ञ आंकलन समिति की बैठक दिनांक 22.09.2022 में की गई चर्चा एवं दिये गये निर्देशानुसार जानकारी निम्नानुसार है :-

- 1— विगत वर्षों में कोविड-19 के संक्रमण के कारण उक्त खदानों से पर्याप्त मात्रा में रेत खनिज की निकासी नहीं की जा सकी है।
- 2— विगत वर्षों में खनिज की मांग कम होने के कारण उक्त खदानों से पर्याप्त मात्रा में रेत खनिज की निकासी नहीं की जा सकी है।
- 3— जिला शाजापुर की नदियों में काली रेत बजरी ही पाई जाती है जिसकी मात्रा बहुत कम है जो पत्थर मिटटी के साथ मिश्रित रूप में पाई जाती है। जिसमें से लगभग 20-25 प्रतिशत रेत ही विक्रय योग्य प्राप्त होती है।
- 4— जिला सर्वेक्षण रिपोर्ट तैयार करने हेतु गठित समिति के द्वारा परीक्षण के दौरान भी उक्त खदानों में दर्शित माईनेवल मात्रा अनुसार रेत खनिज का उल्लेख रिप्लेनिसमेंट प्लान के अध्ययन में भी उक्त खदानों में माईनेवल मात्रा से अधिक रेत खनिज का रिप्लेनिसमेंट होना पाया गया है।

अतः जानकारी अग्रिम कार्यवाही हेतु सादर प्रेषित है।

संलग्न:- उपरोक्तानुसार।

District Survey Report: Shajapur

District Survey Report: Shajapur

1 Introduction

In pursuance to the Gazette Notification, Ministry of Environment, Forest and Climate Change (MoEF& CC), the **Government of India Notification NoS.O. 141 (E) Appendix-X, Dated 15.01.2016 & S.O. 3611 (E) New Delhi, 25th July 2018** laid procedure for preparation of District Survey Report of sand mining or river bed mining. The main purpose of preparation of District Survey Report (DSR) is to identify the Sand resources and developing the sand mining activities along with other relevant data of the district.

The process of making a DSR includes:

- Collection of baseline data from the department
- Development of related maps from satellite and secondary sources
- Understanding river flows and sedimentation vis-à-vis sand mining
- Tabulation and mapping of existing sand mining locations and yield
- Correlation with satellite data for pre and post monsoon sand yield
- Suggesting new locations for sand mining approvals
- Design and Development of DSR as per MoEF guidelines
- Interaction with line department for data / document ownership

For the first time, the Ministry of Environment, Forests and Climate Change (MoEFCC) has released guidelines to monitor and check illegal sand mining in the country.

- Sustainable Sand Management Guidelines (SSMG), 2016 focuses on the management of sand mining, but there was a need to have guidelines for effective enforcement of regulatory provisions and their monitoring.
- The 2020 guidelines are to be enforced simultaneously with the SSMG, 2016, in case of conflict; the new set will hold legal precedence. The Mines and Minerals (Development and Regulation) Act, 1957 has empowered state governments to make rules to prevent illegal mining, transportation and storage of minerals.
- However, there were a large number of illegal mining cases in the country and in some cases, many of the officers lost their lives while executing their duties to curb illegal mining.
- Illegal and uncontrolled illegal mining also leads to loss of revenue to the State and degradation of the environment.

District Survey Report: Shajapur

The fair and rapid advancement of technology in country has enabled surveillance and remote monitoring in the field of mining for the effective monitoring of the mining activities particularly sand mining. States are now utilizing remote sensing to prevent illegal mining. Rules have been made to prevent illegal mining, transportation and storage of minerals but in the recent past, it has been observed that there was large number of illegal mining cases in the country and in some cases, many of the officers lost their lives while executing their duties for curbing illegal mining incidence. The illegal and uncontrolled illegal mining leads to loss of revenue to the State and degradation of the environment. Thus, an effective policy for monitoring of sand mining in the Country has been enforced focusing on the effective monitoring of the sand mining since from the identification of sand mineral sources to its dispatch and end-use by consumers and the general public.

- Source to Destination Monitoring: The new set of guidelines focuses on the effective monitoring of sand mining from the identification of sand mineral sources to its dispatch and end-use by consumers and the general public and look at a uniform protocol for the whole country.
- Constantly monitor mining with drones and night surveillance of mining activity through night-vision drones.
- Audits: States to carry out river audits put detailed survey reports of all mining areas in the public domain.
- Transparency: Online sales and purchase of sand and other riverbed materials (RBM) for transparency in the process.
- Enforcement: It gives directions to states to set up dedicated task forces at district levels.

In cases where rivers become district boundaries or state boundaries, the districts or states sharing the boundary shall constitute the combined task force for monitoring of mined materials, mining activity and participate in the preparation of District Survey Reports (DSR) by providing appropriate inputs.

- Sustainability: Conduct replenishment study for river bed sand in order to nullify the adverse impacts arising due to excessive sand extraction.
- While the Sustainable Sand Mining Guidelines, 2016, require the preparation of District Survey Reports (DSR), which is an important initial step before grant of mining lease, the government has found that the DSRs carried out by state and district

District Survey Report: Shajapur

administrations are often not comprehensive enough, allowing space for illegal mining.

Shajapur district is situated in north-western part of Madhya Pradesh. It is part of Malwa plateau spanning over an area of 6,195 Sq.km. The district is bounded by Rajgarh District on the west, Ratlam district on the north, Jhalawad district of Rajasthan state and by Dewas and Sehore district in the south. The district extends between the parallel of latitude 23°06' and 24°20' north and between meridians of longitude of 75°41' and 77°02" falling in survey of India toposheet No. 46M, 54D. Eastern boundaries of the district have natural division and bounded by rivers Parwati, Kali sindh and Chhoti Kali Sindh respectively.

6 Process of Deposition of sediments in the rivers of the District

Majority of rivers originate from mountains and as they continue their journey with force, through these mountains, the bigger rocks and boulders disintegrate slowly, and over a period of time, starts rolling down as fragments. These fragments become smaller and smaller due to weathering process by water, wind and other rocks. Thus, developed sand particles are transported, washed and stored; and again transported during floods and deposited at river beds and largely on river shores. In case the sand deposits are mined / removed, cavities are formed in their place and again filled during next cycle(s) of deposition.

River sand is preferred as a source of sand because of the following factors:

- Cities tend to be located near rivers so transport costs are low, the energy in a river grinds rocks into gravels and sands,
- Eliminating the costly step of mining, grinding, and sorting of rocks
- The material produced by rivers tends to consist of resilient minerals of angular shape that are preferred for construction.
- Also, offer the advantages of being naturally sorted by grain-size, easily accessible, and able to be transported inexpensively using barges. Despite plentiful supplies of desert sand (Aeolian) which produce materials unsuitable for making concrete.

A meandering stream has a single channel that winds snakelike through its valley. As water flows around these curves, the outer edge of water is moving faster than the inner edge. This creates an erosionsurface on the outer edge (a cut bank) and a depositional surface on the inner edge (a point bar). Where the bends of two meanders meet, they bypass the curve of river, creating an oxbow lake which may then be in-filled with over wash sediment.

Meanders change position by eroding sideways and slightly downstream. The sideways movement occurs because the maximum velocity of the stream shifts toward the outside of the bend, causing erosion of the outer bank. At the same time the reduced current at the inside of the meander results in the deposition of coarse sediment, especially sand. Thus by eroding its outer bank and depositing material along its inner bank, a stream moves sideways without changing its channel size. Due to the slope of the channel, erosion is more effective on the downstream side of a meander.

District Survey Report: Shajapur

The specific gravity of an aggregate is considered as the measure of strength or quality of the material. Specific gravity is defined as the ratio of weight of a given volume of aggregate to the weight of equal volume of water. Aggregates having low specific gravity are generally weaker than those with aggregates having high specific gravity. This property helps in a general identification of aggregates. The specific gravity of (sand) is considered to be around 2.65 to 2.67. Sand particles composed of quartz have a specific gravity between 2.65 to 2.67. While inorganic clays generally range from 2.70 to 2.80. Soils with large amounts of organic matter or porous particles have specific gravity below 2.60 (Some range as low as 2.00).

6.1 Sources of sand

Sand is world's second most consumed natural resource after water. Rapid urbanization and global population growth have created unbound demand for this limited natural resource. With urbanization as key driving factor, construction industry has expanded considerably over the last few decades leading to overuse of river sand for construction purposes. This increasing discrepancy between the need for aggregates in the society and scarcity of natural sand due to exhaustion of resources and environmental considerations, has urged concrete manufacturers to look for a suitable and sustainable alternative fine aggregate. The economical and ecological alternative is manufactured sand.

6.1.1 Natural Sources

Natural sand is produced by natural forces, such as river sand and sea sand. Generally, sand found at foot of mountains is more weathered, containing more mud, organic impurities and light substances. Sea sand often contains shells and other impurities, and its components such as the chlorine, sulfate and magnesium salts may cause corrosion of steel bars. All the components will affect the performance of concrete. Sources of sand can be river bed material, de-siltation pits in reservoirs/dams, agricultural land etc. these can be broadly classifies as:

Following are the natural types of the sand:

- **Pit Sand**

This sand is found as deposits in soil and it is obtained by forming pits into soils. It is excavated from a depth of about 1 m to 2 m from ground level. The pit sand consists of sharp angular grains which are free from salts and it proves to be excellent material for mortar or

District Survey Report: Shajapur

concrete work. For making mortar, the clean pit sand free from organic matter and clay should only be used.

- **River Sand**

This sand is obtained from banks or beds of rivers. The river sand consists of fine rounded grains probably due to mutual attrition under the action of water current. The colour of river sand is almost white. As river sand is usually available in clean condition, it is widely used for all purposes.

6.1.2 Manufactured Sand

Manufactured sand (M-Sand) is artificial sand produced from crushing hard stones into small sand sized angular shaped particles (rock particles with a particle size of less than 4.75 mm and is made by artificial crushing and sieving after soil removal treatment), washed and finely graded to be used as construction aggregate. It is a superior alternative to River Sand for construction purpose. The main technical indicators of artificial sand are particle gradation, fineness modulus, stone powder content, void ratio, apparent density, bulk density, methylene blue value (MB), crushing value index, mica content, light-matter content, etc.

6.2 Sand Mining

Sand Mining is an activity referring to the process of the removal of sand from rivers, streams and lakes.

- Sand is mined from beaches and dredged from river beds.
- There are no official figures for the amount of sand mined illegally, but in 2015-16, there were over 19,000 cases of illegal mining of minor minerals, which include sand, in the country.
- To stop illegal mining, the Ministry of Environment, Forest and Climate Change (MoEF) issued Enforcement and Monitoring Guidelines for Sand mining.
- These guidelines focus on the effective monitoring of the sand mining.

Following considerations shall be kept in mind for sand mining:

- Parts of the river reach that experience deposition or aggradations shall be identified. The Leaseholder/ Environmental Clearance holder may be allowed to extract the sand and gravel deposit in these locations to manage aggradations problem.
- Sand and gravel may be extracted across the entire active channel during the dry season.
- Abandoned stream channels on the terrace and inactive floodplains are to be preferred rather than active channels and their deltas and flood plains. The stream should not be diverted to form the inactive channel.
- Layers of sand which could be removed from the river bed shall depend on the width of the river and replenishment rate of the river.
- Sand shall not be allowed to be extracted where erosion may occur, such as at the concave bank.
- Segments of the braided river system should be used preferably falling within the lateral migration area of the river regime that enhances the feasibility of sediment replenishment.
- Sand and gravel shall not be extracted up to a distance of 1 kilometre (1 km) from major bridges and highways on both sides, or five times (5x) of the span (x) of a bridge/public civil structure (including water intake points) on up-stream side and ten times (10x) the span of such bridge on down-stream side, subjected to a

Abanu
Assessment & Monitoring, M.P.
Bhopal, 2021 (M.P.)

District Survey Report: Shajapur

minimum of 250 meters on the upstream side and 500 meters on the downstream side.

- Sand and gravel could be extracted from the downstream of the sand bar at river bends. Retaining the upstream one to two-thirds of the bar and riparian vegetation is accepted as a method to promote channel stability.
- The flood discharge capacity of the river could be maintained in areas where there is a significant flood hazard to existing structures or infrastructure. Sand and gravel mining may be allowed to maintain the natural flow capacity based on surveyed cross-section history. Alternatively, off-channel or floodplain extraction is recommended to allow rivers to replenish the quantity taken out during mining.
- The Piedmont Zone (Bhabhar area) particularly in the Himalayan foothills, where riverbed material is mined, and this sandy-gravelly track constitute excellent conduits and hold the greater potential for groundwater recharge. Mining in such areas should be preferred in locations selected away from the channel bank stretches.
- Mining depth should be restricted to 3 meters and distance from the bank should be $\frac{1}{4}$ th or river width and should not be less than 7.5 meters.
- Demarcation of mining area with pillars and geo-referencing should be done prior to the start of mining.
- A buffer distance /un-mined block of 50 meters after every block of 1000 meters over which mining is undertaken or at such distance as may be the directed/prescribed by the regulatory authority shall be maintained.
- River bed sand mining shall be restricted within the central $\frac{3}{4}$ th width of the river/rivulet or 7.5 meters (inward) from river banks but up to 10% of the width of the river, as the case may be and decided by regulatory authority while granting environmental clearance in consultation with irrigation department. Regulating authority while regulating the zone of river bed mining shall ensure that the objective to minimize the effects of riverbank erosion and consequential channel migration are achieved to the extent possible. In general, the area for removal of minerals shall not exceed 60% of the mine lease area, and any deviation or relaxation in this regard shall be adequately supported by the scientific report.

District Survey Report: Shajapur

- The mining from the area outside river bed shall be permitted subject to the condition that a safety margin of two meters (1 m) shall be maintained above the groundwater table while undertaking mining and no mining operation shall be permissible below this level unless specific permission is obtained from the Competent Authority. Further, the mining should not exceed nine-meter (3 m) at any point in time.
- The permanent boundary pillars need to be erected after identification of an area of aggradations and deposition outside the bank of the river at a safe location for future surveying. The distance between boundary pillars on each side of the bank shall not be more than 100 meters.

8 Land utilization Pattern in the District: Forest, Agricultural, Mining, etc.,

Land use/land cover (LULC) changes are main issues of universal environment change. The Satellite remote sensing data with their monotonous nature have proved to be rather useful in mapping land use/land cover decorations and changes with time. Quantification of such a change is conceivable through GIS techniques even if the subsequent spatial datasets are of dissimilar scales or resolutions. Such studies have helped in considerate the dynamics of human happenings in space and time. Land use refers to man's activities.

Table 6 Land Use Pattern of the Study Area

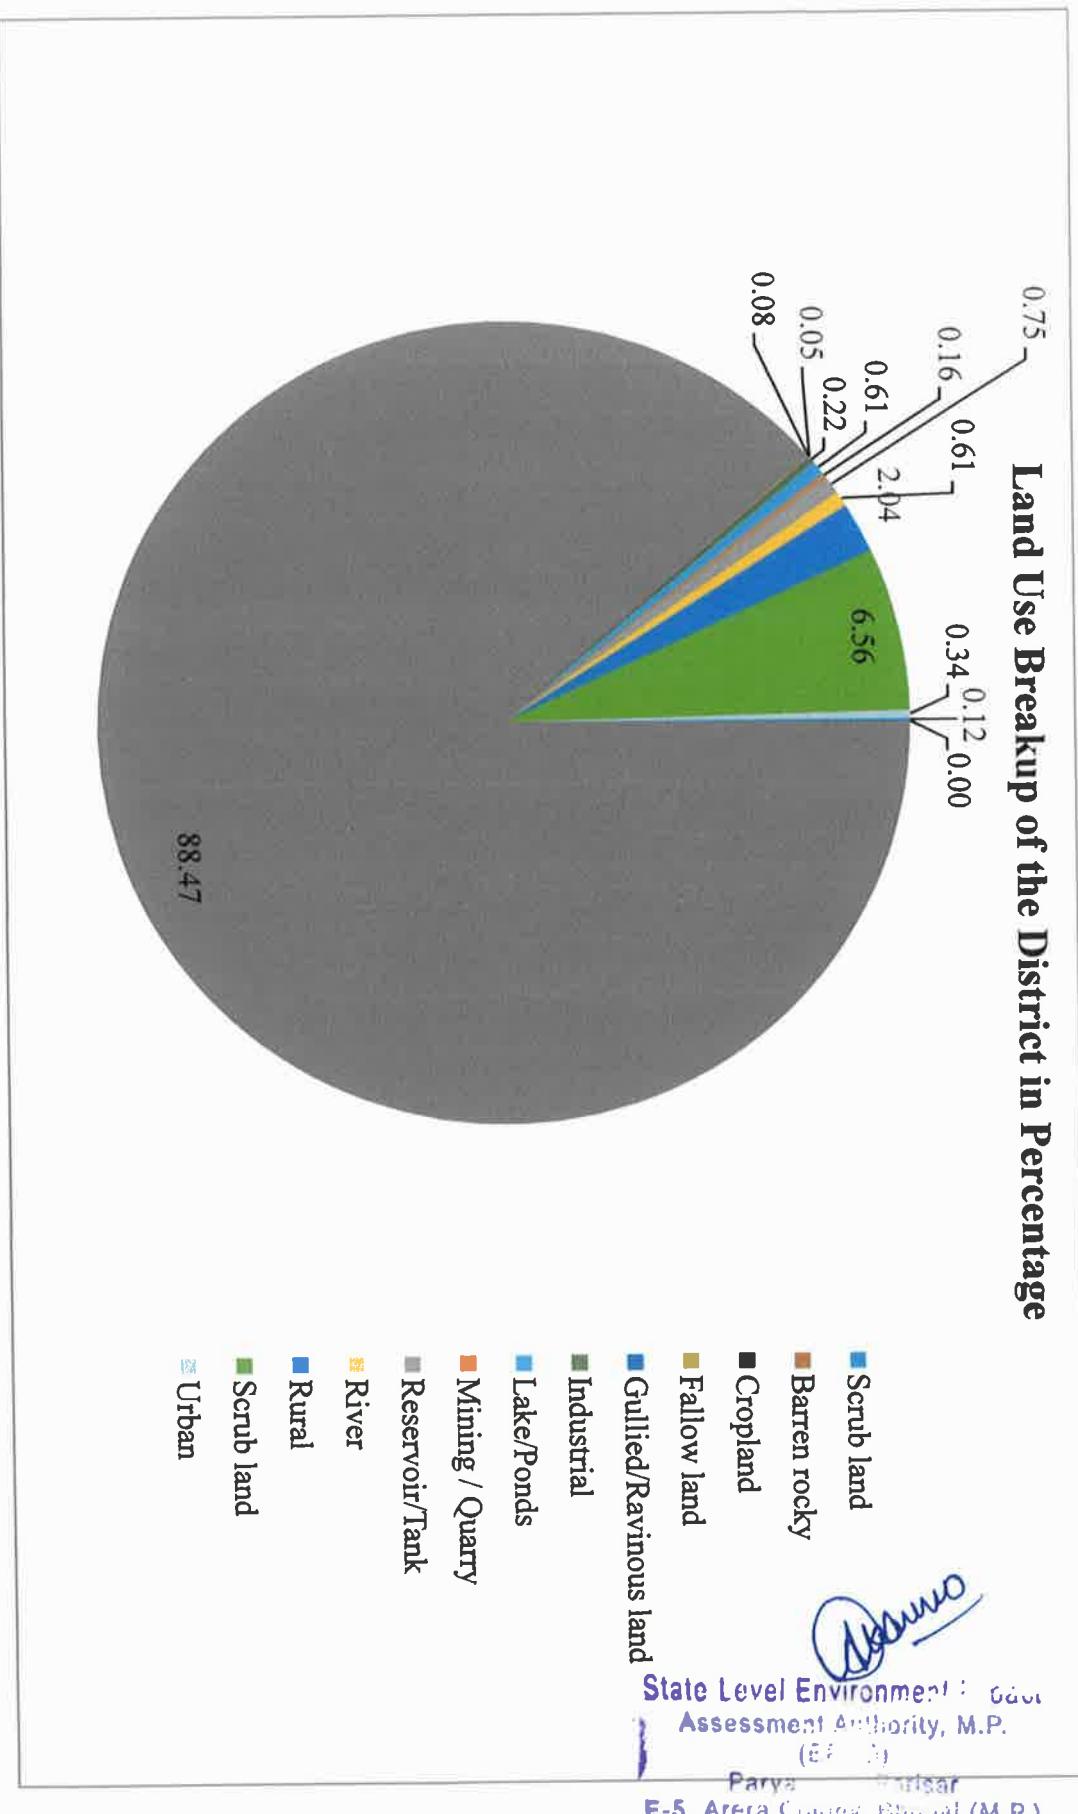

Figure 6 Land Use and Land Cover Breakup of the District

9 Physiography of the District

The entire district is a part of the Deccan Traps flood basalts of the Cretaceous-Paleocene. Alluvium of the recent period is, however, found along the river Parbati in a narrow strip. The district has deep black and shallow black brown and alluvial soils of the northern region. Shajapur is a part of central Madhya Pradesh plateau and Ratlam plateau.

There is a hill tract in the west of Badod town showing scattered hillocks in a north-south direction. The presence of hills in the center has affected the drainage pattern. The height of this tract varies between 500 and 545 meters above the mean sea level and it slopes towards the north.

Shajapur forested upland stretches from north to south in the middle of the district covering considerable portions of Agar Malwa and Shajapur tehsils and a small part of Susner tehsil. It is a part of the Malwa plateau with typical topography. There is a continuous chain of hills throughout the entire region. The height of the region varies between 450 and 530 meters above the mean sea level. The surface height decreases towards the north. Since it is an upland area, a number of seasonal streams originate from this zone and drain mostly towards the east.

The Kali Sindh basin stretches between the southern and northern limits of the district. It occupies the major parts of Susner and Shajapur tehsils and a very small part of Agar tehsil. The southern part of the region is hilly whereas the northern part is plain. The hills gradually decrease in height from south to north. There are a few scattered hillocks in the central and northern parts also. The altitude of the region varies between 450 and 528 meters above the mean sea level. Numerous streams originate from the hilly area and dissect the surface.

Shajapur upland extends over the eastern part of the district covering the entire Shujalpur tehsil and a small segment of Shajapur tehsil. Being a part of the Malwa plateau, it presents a dissected topography. A hill range enters this region from the north and extends towards the south. The southern part of the region is an upland area and northern part is relatively low lying. In the south, the hills are scattered and are eroded by various streams. The height at the region varies between 435 and 507 meters above the main sea level. The 450 meters contour encircles the area along the Newaj River where the small hills are spread, and the Newaj dissects these hills. The eastern part of the region is a low and water dividing line of the western part can be decided by the tributaries of Newaj

District Survey Report: Shajapur

10.1.1 Rainfall of the District and Climate Conditions

10.2 Rainfall

The normal annual rainfall of Shajapur District is 1020.2 mm. Shajapur district receives maximum rainfall during south – west monsoon period i.e. June to September. About 92.3% of the annual rainfall received during monsoon season. Only 7.7% of the annual rainfall takes place between October to May period. Thus surplus water for ground water recharge is available only during the south – west monsoon period. The maximum rainfall received at Shajapur is 987.3 mm and minimum is 865.4 mm.

During the south- west monsoon season the relative humidity generally exceeds 88% (July/ August month). The rest of the year is drier. The driest part of the year is the summer season, when relative humidity is less than 33%. April is the driest month of the year.

10.3 Climatic Conditions

The climate of Shajapur district MP characterised by hot summer and general dryness except during the south west monsoon season. The year may be divided into four seasons. The cold season, December to February is followed by the hot season from March to about the middle of June. The period from the middle of June to September is the south west monsoon season. October and November form the post monsoon or transition period.

The normal maximum temperature recorded during the month of May is 39.9°C and minimum during the month of January 9.6°C. The normal annual means maximum and minimum temperature of Shajapur district is 31.3°C & 35.5°C respectively.

The wind velocity is higher during the pre monsoon period as compared to post monsoon period. The maximum wind velocity is 27.0 km / hr. observed during the month of June and minimum 7.1 km/hr during the month of November. The average normal annual wind velocity of Shajapur district is 15.9 km/hr.

11 Geology of the District

Geologically, the Malwa plateau refers to the volcanic upland south of the Vindhya, which includes the Malwa region and extends east to include the upper basin of the Betwa and the headwaters of the Dhasan and Ken rivers. The region is composed of dry deciduous forests that are home to a number of tribes, most important of them being the Bhils. The Malwa region occupies a plateau in western Madhya Pradesh and south-eastern Rajasthan with Gujarat in the west. To the south and east is the Vindhya Range and to the north are the Bundelkhand uplands. The plateau is an extension of the Deccan Traps, formed between 60 and 68 million years ago at the end of the Cretaceous period.

In this region, the main classes of soil are black, brown and stony soil. The volcanic, clay-like soil of the region owes its black colour to the high iron content of the basalt from which it is formed. The soil requires less irrigation because of high moisture retention capacity. The other two soil types are lighter and have a higher proportion of sand.

12 Drainage and Irrigation Pattern

12.1 Drainage Pattern

Entire Shajapur district lies within Yamuna basin, Chambal sub basin and is drained by prominently northerly flowing rivers like Chhoti Kalisindh, Kali Sindh, Lakhunder Newaj and Parvati. These rivers and their streams give dendritic drainage. The district area is located between surface elevation 335 and 608 msl.

12.2 Irrigation Practices

Irrigation is the artificial application of water to the soil for normal growth of plants. Water is an important determinant factor for production of crops in agriculture sector. Intensive and extensive cultivation of land depends mainly on the availability of water. Medium and minor irrigation schemes are implemented in the state for augmenting the water supply for agriculture. The various sources of irrigation are canals, tanks, tube wells, ordinary wells, springs and channels.

13 Surface Water and Ground water scenario of the District

13.1 Ground Water

Ground Water is found beneath the earth's surface and is an important source of water in most of the Districts in the State. Ground Water is withdrawn for Agriculture, Municipal and industrial use. The depth at which the ground water is called Ground water table.

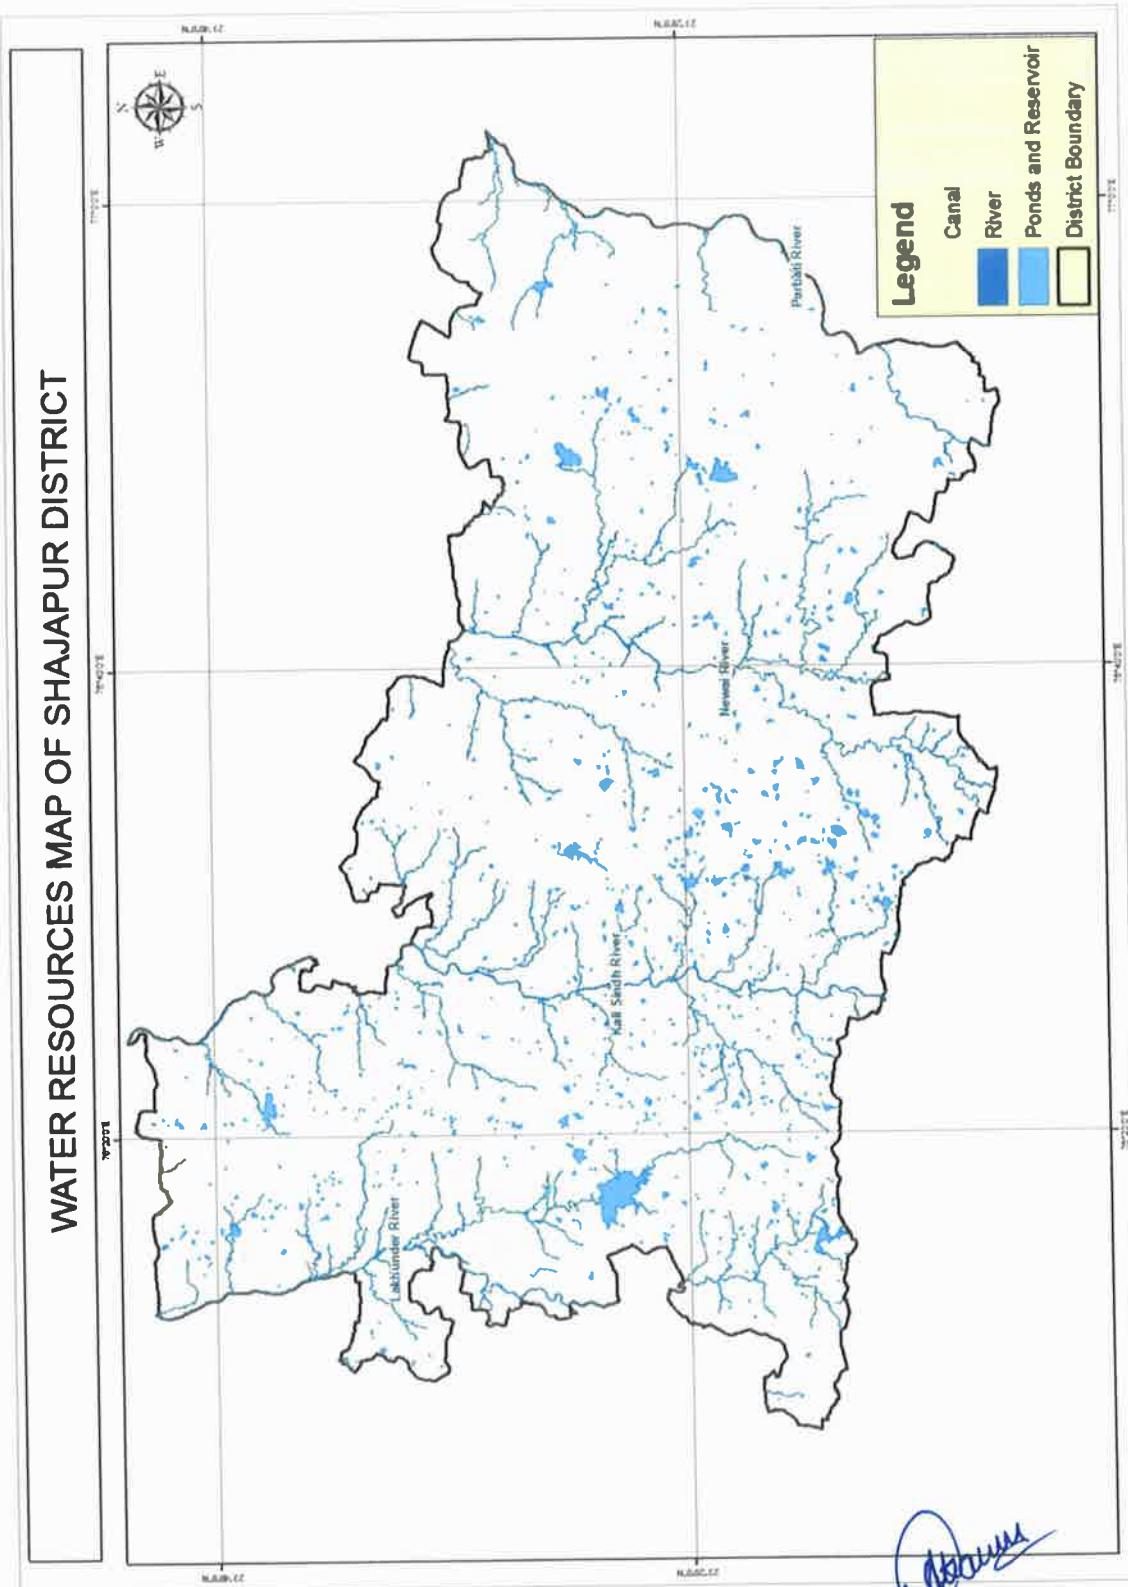

Ground Water occurs in different lava flows having distinctive feature like significant primary porosity in the form of vesicles lava tubes formed due to emanations of gases in weathered lava flows along with fractures, variation vesicles and its vide spatial and temporal with minerals considerable reduced by filling up with minerals like zeolites, calcite, and silica to form amygdale. Alternating sequences of pervious and compact horizon function as a multi aquifer system. Shallow ground water occurs in the weathered vesicular, jointed fractured zones of basaltic flows generally under unconfined conditions at some places under semi confined to confined condition due to the presence of thickly silty clays overlying the jointed rocks in the cases of deepr aquifer. Shallow aquifer also noticed in alluvium occurs along Lakhunda, Kalisindh, Newaj and Parvati river courses .Laterite development on basalt is not extensive except in and around Agar town where the traps have undergone maximum degree of leaching.

13.2 Surface Water

Entire Shajapur district lies within Yamuna basin, Chambal sub basin and is drained by prominently northerly flowing rivers like Chhoti Kalisindh, Kali Sindh, Lakhunder Newaj and Parvati. These rivers and their streams give dendritic drainage. The district area is located between surface elevation 335 and 608 msl.

								Clearance
								Fresh Mine
22	Parbati River Village – Pipalyanagar Khasra No. – 459.503	1.06	47.17	50000 x 1	50000	70000	30000	42000
23	Kalisindh River Village – Devlavihar Khasra No. – 1636	0.94	42.50	40000 x 1	40000	56000	24000	33600
	Total	20.6	43.174 (avg)	830840	830840	1163176	498504	697905.6

Remark: 1 - In shajapur district last 3 year production has been done from wajirpur, chauma, pipalyanagar, semlichacha, sundarsi mines. These mines not included in the list because of new enforcement and monitoring guidelines 2020, these mines fall under 1km distance from the road bridges hence mining will not be possible in these mines.

2 - Sand available in Shajapur district is low quality sand because of stone boulder and soil mixed with sand.

3 - Demand of sand is very less in last 3 years because of Covid-19 and low quality of sand.

4 - Production of sand is very less to nil in sand mines in last 3 years because of tender in the district was terminated and no production has been done.

5 - Sand quantity in the mines in district has been measured by the established committee after field Survey.
